# Games, geometry, and [ the computational complexity of ] finding equilibria 

## Bernhard von Stengel

Department of Mathematics
London School of Economics

## Overview

An introduction to computational complexity, two open problems and a result on equilibrium computation:

- solving simple stochastic games
- finding a Nash equilibrium of a bimatrix game: long Lemke-Howson paths
[joint with Rahul Savani ]

## Computational complexity

Computational complexity of a problem $=$ running time as function of input size $n$ ( $\mathrm{n}=$ bits required to specify problem instance).

Decision problems = decide "yes" or "no"

Example:

## Perfect matching

Input: $\quad$ Bipartite graph $G$ (list of edges).
Question: Does G have a perfect matching?

## Finding a perfect matching

## Finding a perfect matching

Perfect matching?

## "no" - certificate

## The complexity class NP <br> "nondeterministic polynomial time"

A decision problem belongs to NP
if a "yes" answer can be verified quickly, that is, in polynomial time with the help of a nondeterministically found short "certificate".

Example:
Perfect matching $\in$ NP,
("yes"-)certificate = set of matched edges.

## The complexity class co-NP

A decision problem belongs to co-NP
if a "no" answer can be verified quickly.
Example:
Perfect matching $\in \mathbf{c o}-\mathbf{N P}$,
"no"-certificate $=$ node set A so that
$\mid\{b: a \in A,(a, b)$ is an edge $\}|<|A|$,
which exists if the graph has no perfect matching by Hall's marriage theorem.

## The complexity class $P$ "polynomial time"

A decision problem belongs to $\mathbf{P}$
if it can be decided ("yes" or "no") quickly,
that is, in polynomial time $O\left(n^{k}\right)$ for input size $n$,
for some constant k.
(Typically small k, e.g. k=3).

## Perfect matching is in $\mathbf{P}$

Input: Bipartite graph with n nodes on each side. Output: Perfect matching, or "no"-certificate A.

Augmenting-path algorithm:
for each unmatched node $\vee \times n$

- find augmenting path from $v \quad O\left(n^{2}\right)$
- flip matched and unmatched edges
overall:
$\mathrm{O}\left(\mathrm{n}^{3}\right)$

## Start with unmatched node

Find unmatched node

## Get matched edge

## Next unmatched node

Find matched node

Go back along matched edge

Find unmatched node

Flip edges

## Next unmatched node

Find unmatched node

Flip edge

## Next unmatched node

Find matched node

## Go back along matched edge

Find unmatched node

Flip edges, done

## Sitting friends around a table

## = finding a Hamiltonian cycle

## Hamiltonian cycle, $\in$ NP

## Hamiltonian cycle?

## Complexity of Hamiltonian cycle

Input: Graph G
Question: Does G have a Hamiltonian cycle? (= cycle that visits each node once)

Hamiltonian cycle is [widely believed to be] not in co-NP.
[Karp 1975]:
Hamiltonian cycle is NP-complete.

## NP-complete problems

A decision problem is NP-complete
if it is in NP, and if every problem in NP
can in polynomial time be reduced to it.
If an NP-complete problem is in $\mathbf{P}$, then

$$
N P=P
$$

(the \$1,000,000 question,
[ widely believed: NP $\neq P$, NP $\neq$ co-NP ] ).
See: Garey / Johnson, Computers and Intractability: A Guide to Theory of NP-completeness [1979].

## Exponential algorithms

The only known algorithms to decide
NP-complete problems of size n are exponential, with running time $\mathrm{Cn}^{\mathrm{n}}$ for $\mathrm{C}>1$.

Why not use brute force?
E.g. try out all $n$ ! permutations of nodes for Hamiltonian path?

$$
\delta<
$$

## Why polynomial time?

Polynomial time algorithms scale well, e.g. $O\left(n^{3}\right)$ algorithm:
input size increases from
$\Rightarrow$
running time increases from $\mathrm{cn}^{3}$ to $8 \mathrm{cn}^{3}$

## The complexity classes

## The complexity classes

Primes

Matrix games

## The complexity classes

Primes

Simple stochastic games

## Matrix games in NP $\cap$ co-NP

Input: Integer matrix A, rational number q
Question: Does the zero-sum matrix game A have value $\geq q$ ?

In NP / co-NP with mixed strategies for maximizer / minimizer as certificates.

In $\mathbf{P}$ via polynomial-time linear programming algorithm [Khachiyan 1979]

## Primes in NP $\cap$ co-NP

Input: Integer $x$ with $n$ digits
Question: Is x prime?

In co-NP: factors as certificate
In NP: [Pratt 1975]
In $\mathbf{P}$ :
[Agrawal / Kayal / Saxena 2004]
This is not factoring in polynomial time!

# Game theoretic-problems in NP $\cap$ co-NP but not known to be in $P$ 

Parity games:
Used in logic and verification, equivalent to model checking for modal mu-calculus.

Mean-payoff games:
Used in competitive analysis of online algorithms.
Simple stochastic games:
More general than both.

## Simple stochastic game

= directed graph with
out-degree-2 nodes:

w.l.o.g. [Condon 1992]: stopping game (ends with prob. 1)

## Simple stochastic game

## Certificate: strategies and payoffs

## Solving simple stochastic games

$\begin{array}{ll}\text { Input: } & \text { Simple stochastic game, node } u, \\ & \text { rational number q }\end{array}$
Question: When started at $u$, does the game have value $\geq q$ ?

In NP / co-NP with pure Markov strategies for max / min and a value for each node as certificates.

But: no polynomial-time algorithm known!

## Strategy improvement algorithm

## [Hoffman / Karp 1966]

Start with arbitrary strategy s of max
loop: Let $t$ be best response of $\min$ to $s$.
Let s' be obtained from s by switching all max-choices with better value(s,t).
if $s \neq s^{\prime}$ repeat with $s \leftarrow s^{\prime}$

Each iteration quick, but number of iterations not known to be polynomial (nor exponential).

## start with some max strategy s

## best response t

## switch for max

## change to s'

## best response t'

## switch for max

## change to s"

## (same) best response t'

## no change for max, done

## Recent progress

[Gärtner / Rüst 2005]
A simple stochastic game can be expressed as a P-matrix LCP.

LCP = Linear Complementarity Problem
P-matrix: LCP has always unique solution.
Polynomial-time interior-point methods for some P-matrix LCPs known [Ye 2002].

## Finding a Nash equilibrium

$\begin{array}{ll}\text { Input: } & \text { Bimatrix game }(\mathrm{A}, \mathrm{B}) . \\ \text { Output: } & \text { A Nash equilibrium }(\mathrm{x}, \mathrm{y}) .\end{array}$

This is a (NP) search problem.

The decision problem is trivial!

## Finding a Nash equilibrium

Input: $\quad$ Bimatrix game ( $\mathrm{A}, \mathrm{B}$ ).
Output: A Nash equilibrium (x,y).

This is a (NP) search problem.

No polynomial-time algorithm known!

## Decision problems for Nash equilibria

[Gilboa / Zemel 1989]
The following problems are NP-complete:

Input: Bimatrix game, rational number q .
Question: Does the game have a Nash equilibrium with payoff $\geq q$ to player 1 ?

Input: Bimatrix game.
Question: Does the game have a unique Nash equilibrium?

## Long Lemke-Howson paths

[Savani / von Stengel 2006]

The Lemke-Howson algorithm for finding one Nash equilibrium of a bimatrix game may take exponential time.

## Nash equilibria of bimatrix games

$$
A=\begin{array}{ll}
3 & 3 \\
2 & 5 \\
0 & 6
\end{array}
$$

## Nash equilibrium =

pair of strategies $\mathrm{x}, \mathrm{y}$ with
x best response to y and
y best response to x .

## Mixed equilibria

$$
\begin{array}{ll}
A=\begin{array}{ll}
3 & 3 \\
2 & 5 \\
0 & 6
\end{array} & B=\begin{array}{ll}
1 & 0 \\
0 & 2 \\
4 & 3
\end{array} \\
x=\begin{array}{c}
0 \\
1 / 3 \\
2 / 3
\end{array} & y^{\top}=\begin{array}{ll}
1 / 3 & 2 / 3 \\
\hline y=\begin{array}{l}
3 \\
4 \\
4
\end{array} & x^{\top} B=8 / 3 \\
\hline
\end{array}
\end{array}
$$

Best response polytope $\mathbf{Q}$ for player 2

$$
\begin{aligned}
& \begin{array}{l}
\text { (1) } \left.\begin{array}{ll}
\mathbf{y}_{4} & \mathbf{y}_{5} \\
3 & 3 \\
\text { (2) } & 2 \\
2 & 5 \\
\text { (3) } & 0
\end{array}\right]=\mathrm{A}
\end{array} \\
& \mathbf{Q}=\left\{\left(\mathrm{y}_{4}, \mathrm{y}_{5}\right) \mid\right. \\
& \text { (1): } 3 \mathrm{y}_{4}+3 \mathrm{y}_{5} \leq 1 \\
& \text { (2): } 2 \mathbf{y}_{4}+5 \mathbf{y}_{5} \leq 1 \\
& \text { (3): } \quad 6 \mathrm{y}_{5} \leq 1 \\
& \begin{array}{cc}
\text { (4): } & \mathrm{y}_{4} \\
\text { (5): } & \\
& \\
\mathrm{y}_{5} \geq 0
\end{array} \\
& Q=\{y \mid A y \leq 1, y \geq 0\}
\end{aligned}
$$

Best response polytope $\mathbf{Q}$ for player 2

$$
\begin{aligned}
& \begin{array}{l}
\text { (1) } \left.\begin{array}{ll}
\mathbf{y}_{4} & \mathbf{y}_{5} \\
3 & 3 \\
\text { (2) } & 2 \\
2 & 5 \\
\text { (3) } & 0
\end{array}\right]=\mathrm{A}
\end{array} \\
& \mathbf{Q}=\left\{\left(\mathrm{y}_{4}, \mathrm{y}_{5}\right) \mid\right. \\
& \text { (1): } 3 \mathrm{y}_{4}+3 \mathrm{y}_{5} \leq 1 \\
& \text { (2): } 2 \mathbf{y}_{4}+5 \mathbf{y}_{5} \leq 1 \\
& \text { (3): } \quad 6 \mathrm{y}_{5} \leq 1 \\
& \left.\begin{array}{lll}
\text { (4): } & \mathrm{y}_{4} & \geq 0 \\
\text { (5): } & & \mathrm{y}_{5} \geq 0
\end{array}\right\} \\
& Q=\{y \mid A y \leq 1, y \geq 0\}
\end{aligned}
$$

Best response polytope $\mathbf{P}$ for player 1

$$
P=\left\{x \mid x \geq 0, x^{\top} B \leq 1\right\}
$$

Drop label 3

## Why Lemke-Howson works

LH finds at least one Nash equilibrium because

- finitely many "vertices"
for nondegenerate (generic) games:
- unique starting edge given missing label
- unique continuation
$\Rightarrow$ precludes "coming back" like here:

## Complexity of Lemke-Howson

- finds at least one Nash equilibrium, pivots like Simplex algorithm for linear programming
- Simplex may be exponential [Klee-Minty cubes]
- exponentially many steps of Lemke-Howson for any dropped label?
- Yes! This is our result.

## Our result

There are $d \times d$ games with exactly one Nash equilibrium, for which the Lemke-Howson algorithm takes $\geq \phi 3 \mathrm{~d} / 4$ many steps for any dropped label (with Golden Ratio $\quad \phi=(\sqrt{ } 5+1) / 2=1.618 \ldots$..)

We will show this using dual cyclic polytopes.

## Vertices as bit patterns

## Vertices as bit patterns

Q

## Dual cyclic polytopes

- vertices = strings of $\mathbf{n}$ bits with $\mathbf{d}$ bits "1",
- no odd substrings 010, 01110, 0111110, ... [Gale evenness]

Example: $\quad \mathrm{d}=4, \mathrm{n}=6 \quad \mathrm{~d}=2, \mathrm{n}=6 \quad(4 \times 2$ game $)$

| 111100 | 000011 |
| :--- | :--- |
| 111001 | 000110 |
| 110110 | 001100 |
| 110011 | 011000 |
| 101101 | 110000 |
| 100111 | 100001 |
| 011110 |  |
| 011011 |  |
| 001111 |  |

## Permuted labels

P = dual cyclic polytope in dimension d with 2d facets

only one non-artificial equilibrium:

$$
\begin{aligned}
& 000000111111 \\
& 111111000000
\end{aligned}
$$

Lemke-Howson will take long to find it!

A(4) = path for $\mathrm{d}=4$, label 1

## $B(6)=$ path for $\mathrm{d}=6$, label 12

## $A(4)$ is prefix of $B(6)$

$A(6)=$ path for $d=6$, label 1

$B(6)$ is prefix of $A(6)$

Suffix of $A(6)=C(6)=A(4)+B(6)$

## Recurrences for longest paths

$\mathbf{A}(\mathrm{d})=$ LH path dropping label 1 in dim d
$B(d)=$ LH path dropping label 2 d in dim d
$C(d)=$ suffix of $A(d)$
lengths of
$B(2) C(2) A(2) B(4) C(4) A(4) B(6) C(6) A(6) \ldots$
are the Fibonacci numbers
$\begin{array}{llllllllll}2 & 3 & 5 & 8 & 13 & 21 & 34 & 55 & 89 & \ldots\end{array}$

## Exponential path lengths

longest paths: drop label 1 or 2 d , paths $\mathrm{A}(\mathrm{d})$, $\mathrm{B}(\mathrm{d})$ path length $\Omega\left(\phi^{3} \mathrm{~d} / 2\right)$
with Golden Ratio $\phi=(\sqrt{ } 5+1) / 2=1.618 \ldots$
shortest paths: drop label $3 \mathrm{~d} / 2$, path $\mathrm{B}(\mathrm{d} / 2)+\mathrm{B}(\mathrm{d} / 2+2)$
path length $\Omega\left(\phi^{3 \mathrm{~d} / 4}\right)=\Omega(1.434 \ldots \mathrm{~d})$

## Summary and extensions

- NE of a bimatrix game = combinatorial polytope problem
- label dual cyclic polytopes, equilibrium at end of exponentially long paths
- but: fully mixed equilibrium easily guessed by support enumeration algorithms
- can extend to $\mathrm{d} \times 2 \mathrm{~d}$ games with hard-to-guess support (exponentially many guesses on average) and exponentially long paths

The following song is a cover version of an original by Billy Joel, "The longest time".

This version by Daniel Barrett, who wrote it as a graduate student at Johns Hopkins University, "on May 1, 1988, during a difficult Algorithms II final exam", and subsequently recorded it.

Woh oh-oh-oh find the longest path
Woh oh-oh find the longest path.
If you say P is NP tonight
there would still be papers left to write
I have a weakness
I'm addicted to completeness
and I keep searching for the longest path.

The algorithm I would like to see is of polynomial degree but it's elusive nobody has found conclusive evidence that we can find the longest path.

I have been
hard working for so long
I swear it's right
and he marks it wrong
somehow I feel
sorry when it's done
GPA 2.1
is more than I hope for
Garey, Johnson,
Karp and other men (and women, too)
try to make it order $\mathrm{N} \log \mathrm{N}$
am I a mad fool
if I spend my life in grad school
forever following the longest path
Woh oh-oh-oh find the longest path
Woh oh-oh find the longest path
Woh oh-oh find the longest path.
